

CS 17700

Functions

Week 5

Functions

- Previously, we have used function: range, eval, sqrt, etc.
- Functions allow grouping statements together under a (function name) that can be executed by calling the function
- Functions are a collection of instructions that perform a task as:
 - Printing your name and course
 - Calculating the average of a set of numbers
 - Editing a picture or video

Functions

- Like in algebra, a function is a kind of “box” into which you put one value and out comes another. We represent (“denote”) a function by a name (in math we use f or F).

Why to use a function?

- If we define a function to perform a task, then we will write it **once** but we can use it (or call it) **many times**.
- Functions can make a program easier to read and debug.
- Functions can make a program shorter as their use can eliminate repetitive code.
- Functions allow that future changes need to be only made in one place.
- Dividing a program into functions allows one to debug parts one at a time.
- Well-designed functions are often useful in other programs and can allow the reuse of code.

How to write functions?

```
def functionName():  
    statement #1  
    statement #2  
    ...
```

- Indentation is very important in Python, it marks the beginning of function body
- Python will give errors if your function is not properly indented

It is a programming practice to define a function that is called main to call the other functions in our program

Example

```
def SayHello() :  
    print("Hello world!")  
  
    print("--From Python")  
  
SayHello()
```

Note: 1. Don't forget the colon(:)

2. Align the statements in one function

Functions: Arguments

- A function may or may not receive one or more argument

No Argument

```
def Greet():  
    print("Hello Jack")  
  
def main():  
    Greet()
```

One Argument

```
def GreetWithArg(message):  
    print(message)  
  
def main():  
    msg = "Hello Jack"  
    GreetWithArg(msg)
```

Functions: Arguments

- A function argument can be:
 1. A value
 2. Expression
 3. A variable

```
def Sum(a, b):  
    total = a + b  
    print(total)
```

```
def main():  
    x = 5  
    y = 10  
    Sum(4, 10) ←  
    Sum(x+2, y-3) ←  
    Sum(x, y) ←
```

Arguments are values

Arguments are expressions

Arguments are variables

Function: Arguments

- On function call, Python assigns the value of the argument to the variable declared in function
- When the argument passed to a function is the value of a variable, the name of that variable is irrelevant to the function

```
def Sum(a, b):  
    total = a + b  
    print(total)
```

```
def main():  
    x = 5  
    y = 10  
    Sum(x, y)
```

a

b

- The value of **x** and **y** were put into **a** and **b** respectively via function call.
- **x** and **y** are called: local variables to function main
- **a** and **b** are called: local variables to function Sum

Function: Arguments

- The name of argument passed to functions may or may not match the name of the variable used in the function

```
def Sum(a, b):  
    total = a + b  
    print(total)
```

```
def main():  
    a = 5  
    b = 10  
    Sum(a, b)
```

a: local variable to Sum

a

b: local variable to Sum

b

- The value of **a** and **b** that **are local to function main** were put into the local variables **a** and **b** respectively via function call.

Functions: Returned Values

- Functions may return values (example: the result of a computation).
- Returned values can be :
 1. Printed
 2. Used in assignment statement
 3. Used in expression

```
def Average (a, b) :  
    return (a+b)/2  
  
def main () :  
    print (Average (10,2) )  
    avg = Average (3, 4)  
    Total = Average (4,3) * 0.95
```

Functions with Multiple Returned Values

- Functions in Python may return multiple values

```
def getabc():  
    a = "Hello"  
    b = "World"  
    c = "!"  
    return a,b,c  
def main():  
    s1, s2, s3 = getabc()
```

Example

```
def Sum(a, b, c):  
    return (a+b+c)  
  
def Greet(name, GPA):  
    print("Hello", name)  
    print("You have a GPA of ", GPA)  
  
def Div(a, b):  
    return a/b  
  
def Mul(a, b):  
    return a*b  
  
def main():  
    x = 3  
    y = 4  
    z = 2  
    myStr = "Mike"  
    Total = Sum(x, y, z)  
    print (Greet(myStr))  
    Result = Sum(x, y, z)+ Mul(x, y) - Div(y, z)
```

Functions that Modify Variables (1)

- What is the output of the following program:

```
def Bonus(grade):  
    grade = grade + 10  
  
def main():  
    myGrade = 75  
    print (myGrade)  
    Bonus(myGrade)  
    print (myGrade)  
  
main()
```

Output: 75
75

Why?

Functions that Modify Variables (1)

- **myGrade** is an argument passed to function Bonus.
- **myGrade** is a numeric data type, also called immutable, that is a function cannot modify its value. In this case, only the value of myGrade matters.
- The function call will put the value of **myGrade** into **grade**
- **grade** is only known '**locally**' to the function Bonus
- If you want to export the value from function Bonus back to main, function Bonus **MUST** use a **return** statement
- Then you can use the function call in an assignment statement

Bonus function now returns a value

```
def Bonus(grade):  
    grade = grade + 10  
    return grade  
  
def main():  
    myGrade = 75  
    print(myGrade)  
    myGrade = Bonus (myGrade)  
    print(myGrade)  
  
main()
```

Output: 75
85

Functions that Modify Variables (2)

- What is the output of the following program:

```
def Bonus(gradeList):  
    for i in range(len(gradeList)):  
        gradeList[i] = gradeList[i] +  
10  
  
def main():  
    myGrades = [75, 90,80]  
    print (myGrades)  
    Bonus(myGrades)  
    print (myGrades)  
  
main()
```

Output: [75, 90, 80]
[85, 100, 90]

Why?

Functions that Modify Variables (2)

- **myGrades** is an argument passed to function Bonus.
- **myGrades** is list, in Python, lists are mutable, that is a function can modify its value.
- **gradesList** is only known **'locally'** to the function Bonus.
- The function call will work on the actual contents of **myGrades** under the name **gradesList**

Functions with more than one return statement

```
def Bonus(grade):  
    grade = grade + 10  
    return grade  
    grade = grade + 10  
    return grade  
  
def main():  
    myGrade = 75  
    print(myGrade)  
    myGrade = Bonus (myGrade)  
    print(myGrade)  
  
main()
```

Output: 75
85

A function call terminates once a return statement is encountered.

What can go wrong?

- **If your parrot is dead, consider this:**
 - Did you use the exact same names (case, spelling)?
 - All the lines in the block must be indented, and *indented* the same amount.
 - Variables in the command area don't exist in your functions, and variables in your functions don't exist in the command area.
 - The computer can't read your mind.
 - It will only do exactly what you tell it to do.
 - In fact, programs always “work,” but maybe not how you intended!

split() function

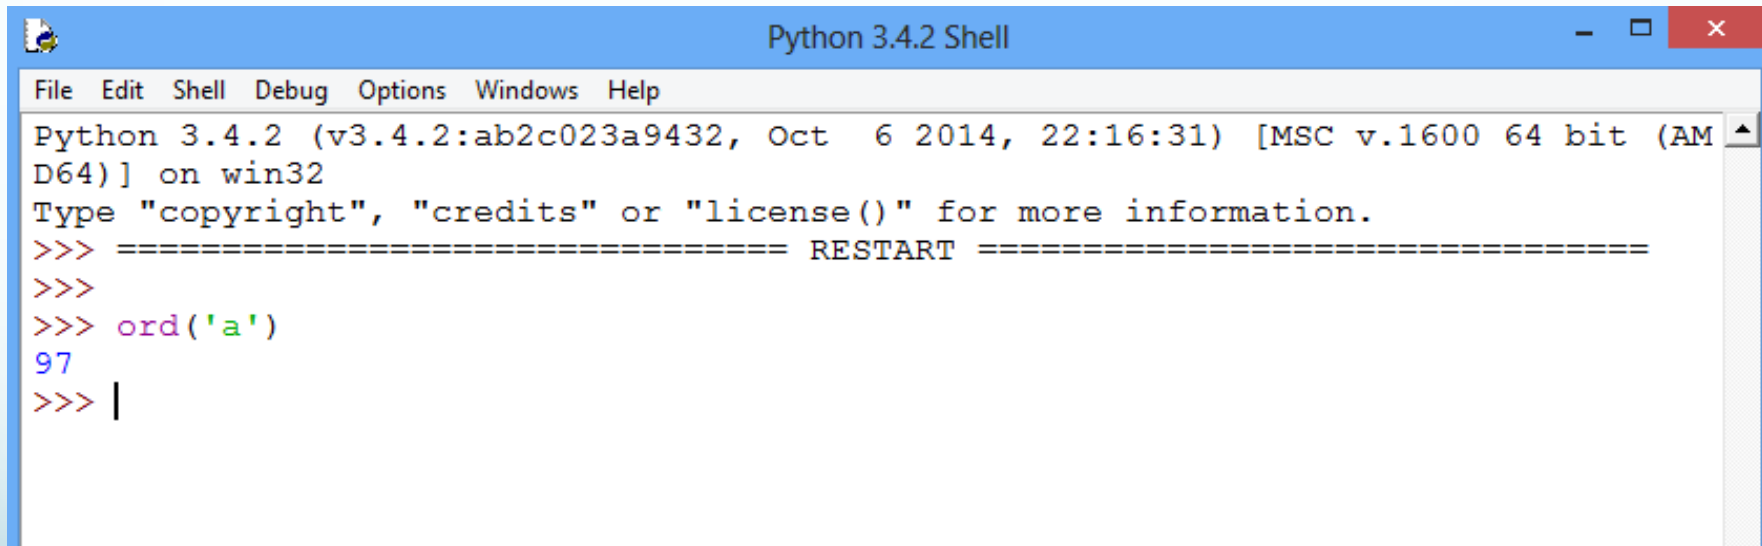

- `str.split([delimiter])`: Return a list of the words in the string, using *delimiter* as the delimiter string, i.e. `'1<>2<>3'.split('<>')` returns `['1', '2', '3']`
- If *delimiter* is not specified or is `None`, whitespace will be considered as delimiter, i.e. `' 1 2 3'.split()` returns `['1', '2', '3']`

What is ASCII ?

- **ASCII** (American Standard Code for Information Interchange) is the most common format for text files in computers and on the Internet. In an **ASCII** file, each alphabetic, numeric, or special character is represented with a 7-bit binary number (a string of seven 0s or 1s). 128 possible characters are defined.

ord() function

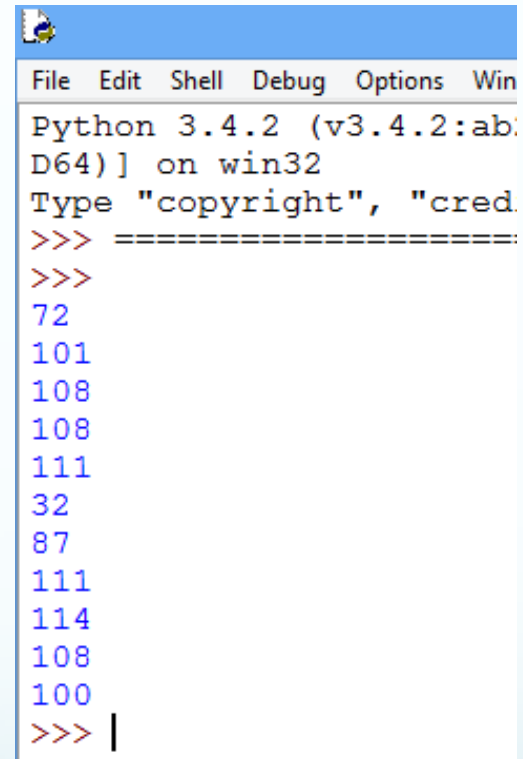

- Some times it is require to convert a string to ASCII value and **ord('single-char')** inbuilt function will give python this capability.

```
Python 3.4.2 Shell
File Edit Shell Debug Options Windows Help
Python 3.4.2 (v3.4.2:ab2c023a9432, Oct 6 2014, 22:16:31) [MSC v.1600 64 bit (AMD64)] on win32
Type "copyright", "credits" or "license()" for more information.
>>> ===== RESTART =====
>>>
>>> ord('a')
97
>>> |
```

Example

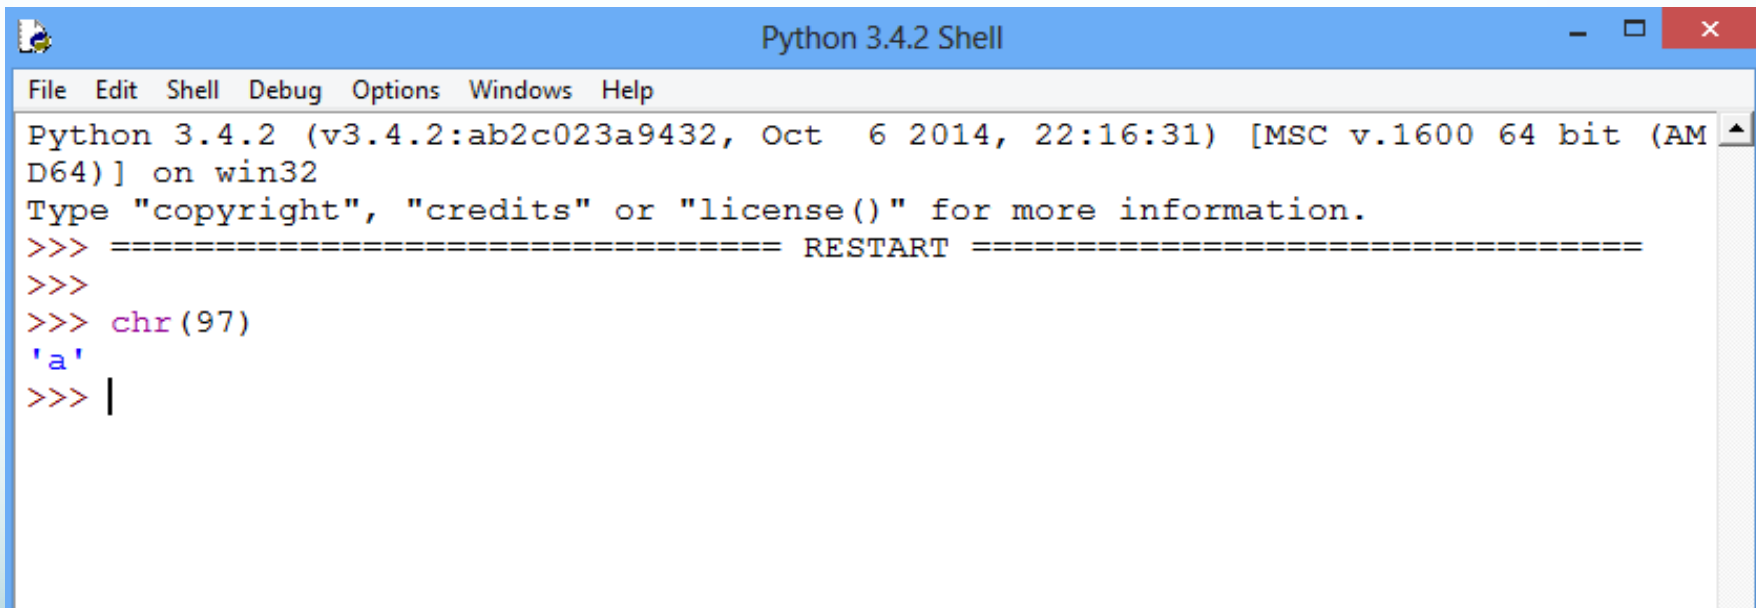

```
string='Hello World'  
for i in string:  
    print(ord(i))
```

```
File Edit Shell Debug Options Win  
Python 3.4.2 (v3.4.2:ab  
D64)] on win32  
Type "copyright", "cred  
>>> =====  
>>>  
72  
101  
108  
108  
111  
32  
87  
111  
114  
108  
100  
>>> |
```

chr() function

- Some times it requires to convert an ASCII value to its corresponding character and **chr(ASCII value)** in-built function will give python this capability.

```
Python 3.4.2 Shell
File Edit Shell Debug Options Windows Help
Python 3.4.2 (v3.4.2:ab2c023a9432, Oct 6 2014, 22:16:31) [MSC v.1600 64 bit (AMD64)] on win32
Type "copyright", "credits" or "license()" for more information.
>>> ===== RESTART =====
>>>
>>> chr(97)
'a'
>>> |
```

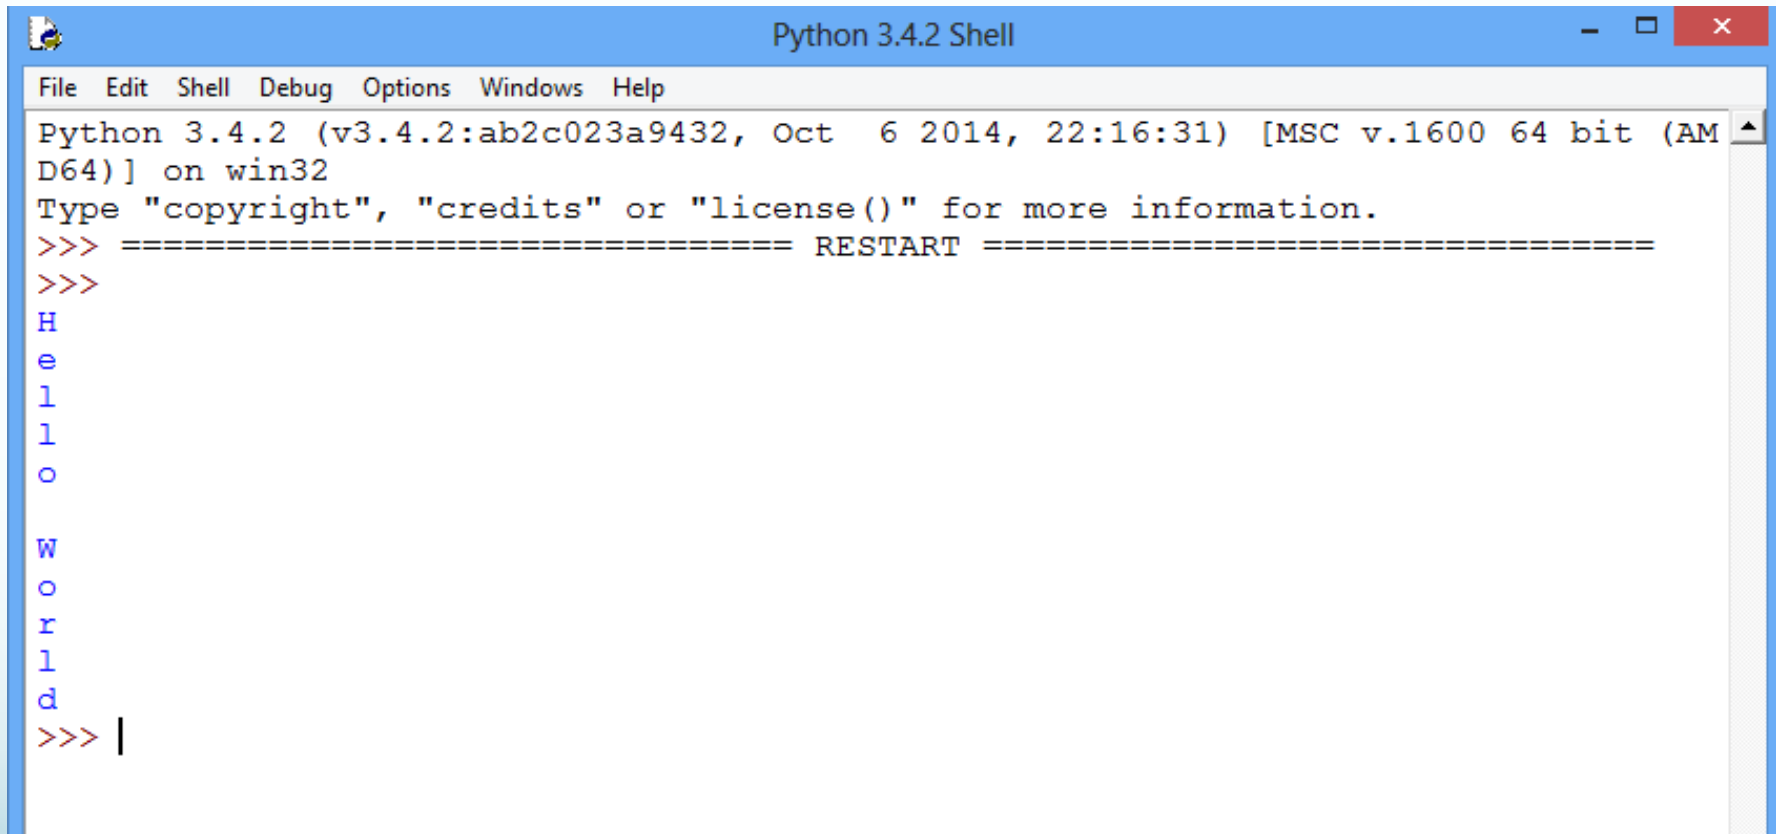

Example

```
list_ascii=[72, 101, 108, 108, 111, 32, 87, 111, 114,  
108, 100]
```

```
for i in list_ascii:
```

```
    print(chr(i))
```

Output of previous example

```
Python 3.4.2 Shell
File Edit Shell Debug Options Windows Help
Python 3.4.2 (v3.4.2:ab2c023a9432, Oct 6 2014, 22:16:31) [MSC v.1600 64 bit (AMD64)] on win32

Other String functions

- `s.capitalize()` – Copy of `s` with only the first character capitalized
- `s.title()` – Copy of `s`; first character of each word capitalized
- `s.center(width)` – Center `s` in a field of given width
- `s.count(sub)` – Count the number of occurrences of `sub` in `s`
- `s.find(sub)` – Find the first position where `sub` occurs in `s`

Other String functions(con't)

- `s.join(list)` – Concatenate list of strings into one large string using `s` as separator
- `s.ljust(width)` – Like `center`, but `s` is left-justified
- `s.lower()` – Copy of `s` in all lowercase letters
- `s.lstrip()` – Copy of `s` with leading whitespace removed
- `s.replace(oldsub, newsub)` – Replace occurrences of `oldsub` in `s` with `newsub`

Other String functions(con't)

- `s.rfind(sub)` – Like `find`, but returns the right-most position
- `s.rjust(width)` – Like `center`, but `s` is right-justified
- `s.rstrip()` – Copy of `s` with trailing whitespace removed
- `s.split()` – Split `s` into a list of substrings
- `s.upper()` – Copy of `s`; all characters converted to uppercase

QUESTIONS???
